Keywords: target coverage, wireless sensor networks, centralized method, disjoint cover sets, lifetime optimization.

Abstract: A problem that has received a lot of interest in wireless sensor networks (WSN) is lifetime optimization. Indeed, in WSN each sensor node is battery powered and it is not convenient to recharge or replace the batteries in many cases, especially in remote and hostile environments. In this paper, we introduce an efficient energy-aware algorithm to enhance the lifetime of WSN by i) organizing/clustering the sensor nodes into disjoint cover sets where each cover set is capable of monitoring all the targets of the region of interest and ii) scheduling these cover sets successively/periodically. This study differs from previous works for the following reasons: i) it achieves near optimal solutions compared to the optimal ones obtained by the exact method and ii) unlike existing algorithms that construct gradually cover sets one after the other, our algorithm builds the different sets in parallel. Indeed, at each step of the clustering process, the algorithm attempts to add to each cover set a sensor capable of monitoring the most critical target (a critical target is defined to be the one covered by the smallest set of sensors). The choice of a sensor to be placed/clustered in each cover set is based on solving a linear assignment problem. The proposed algorithm provides a lower bound K_{min} of the optimal number of disjoint cover sets K_{opt} . Intuitively, the upper bound K_{max} of the optimal value is given by the size of the smallest set of sensors covering a target. We deduce K_{opt} by performing a binary search procedure. At each step of the binary search process, we check if there exists a partition of the sensors in K cover sets by solving an integer programming problem. Simulation results show the efficiency of our algorithm.

1 INTRODUCTION

Recent years have witnessed significant advances in wireless sensor networks which emerge as one of the most promising technologies for the 21st century (Akyildiz et al., 2002). In fact, they present huge potential in several domains ranging from health care applications to military applications. A sensor network is composed of a large number of tiny sensing devices deployed in a region of interest. Each device has processing and wireless communication capabilities, which enable to sense its environment, to compute, to store information and to deliver report messages to a base station. One of the main design challenges in Wireless Sensor Networks (WSN) is to prolong the system lifetime, while achieving acceptable quality of service for applications. Indeed, sensor nodes have limited resources in terms of memory, energy and computational powers.

Since sensor nodes have limited battery life and without being able to replace batteries, especially in remote and hostile environments, it is desirable that a

WSN should be deployed with high density and thus redundancy can be exploited to increase the lifetime of the network. In such a high density network, if all sensor nodes were to be activated at the same time, the lifetime would be reduced. Consequently, future software may need to adapt appropriately to achieve acceptable quality of service for applications. In this paper we concentrate on the target coverage problem, with the objective of maximizing the network lifetime by using an adaptive scheduling. We assume that sensors are randomly deployed for monitoring a set of targets with known locations and we also assume the sensors have location determination capabilities. We propose energy-aware centralized approach that selects mutually exclusive sets of sensor nodes, where the members of each of those sets together completely cover the monitored targets. The intervals of activity are the same for all sets, and only one of the sets is active at any time to provide continuous service while the remaining sets are scheduled to sleep. The objective, is to maximize the number of cover sets to increase the system's service life. Scheduling and

grouping sensors into disjoint sets is done by the base station, which informs every sensor of the time intervals to be activated.

The major contribution of this paper is the design of a new near optimal algorithm for lifetime optimization in WSN. Unlike existing approaches that construct gradually cover sets one after the other, the proposed algorithm builds the different sets in parallel. Indeed, at each step of the clustering process, the algorithm attempts to add to each cover set a sensor capable of monitoring the most critical target. The choice of sensor to be placed/clustered in each cover set is based on solving a linear assignment problem in polynomial time using the Hungarian algorithm. Our approach provides a lower bound K_{min} of the optimal number of disjoint cover sets K_{opt} . Intuitively, the upper bound K_{max} of the optimal value is given by the size of the smallest set of sensors covering a target. We deduce K_{opt} by performing a binary search between K_{min} and K_{max} . At each step of the search process we check if there exists a partition of the sensors in K cover sets by solving an integer programming problem.

The remainder of the paper is organized as follows. Section 2 reviews the related work in the field. Section 3 is devoted to the description of the target coverage problem and explains the basics of our algorithm illustrated by an example. Then we express the time complexity of the algorithm. We also present how to compute the optimal number of disjoint cover sets by solving integer programming problems successively. Section 4 shows the simulation results, that fully demonstrate the usefulness of the proposed algorithm. Finally, we give concluding remarks in Section 5.

2 RELATED WORK

Various approaches, including centralized, distributed and localized algorithms, have been proposed to extend the network lifetime. For instance, in order to hide the occurrence of faults, or the sudden unavailability of sensor nodes, some distributed algorithms have been developed in (Gallais et al., 2006; Tian and Georganas, 2002; Ye et al., 2003; Zhang and Hou, 2005; Heinzelman et al., 2002). The scheduling information is disseminated throughout the network and only sensors in the active state are responsible for monitoring all targets, while all other nodes are in a low-energy sleep mode. The nodes decide cooperatively which of them will remain in sleep mode for a certain period of time.

In this paper we focus on centralized algorithms

because distributed algorithms are outside the scope of our work. Note that centralized coverage algorithms have the advantage of requiring very low processing power from the sensor nodes which have usually limited processing capabilities. Moreover, a recent study conducted in (Padmavathy and Chitra, 2010) concludes that there is a threshold in terms of network size to switch from a localized to a centralized algorithm. Indeed the exchange of messages in large networks may consume a considerable amount of energy in a localized approach compared to a centralized one.

Power efficient centralized schemes differ according to several criteria (Cardei and Wu, 2006), such as the coverage objective (target coverage or area coverage), the node deployment method (random or deterministic) and the heterogeneity of sensor nodes (common sensing range, common battery lifetime). The major approach is to divide/organize the sensors into a suitable number of set covers where each set completely covers an interest region and to activate these set covers successively.

First algorithms proposed in the literature consider that the cover sets are disjoint: a sensor node appears in exactly one of the generated cover sets. For instance Slijepcevic and Potkonjak (Slijepcevic and Potkonjak, 2001) propose an algorithm which allocates sensor nodes in mutually independent sets to monitor an area divided into several fields. Their algorithm constructs a cover set by including in priority the sensor nodes which cover critical fields, that is to say fields that are covered by the smallest number of sensors. The time complexity of their heuristic is $O(n^2)$ where n is the number of sensors. (Cardei et al., 2002) present a graph coloring technique to achieve energy savings by organizing the sensor nodes into a maximum number of disjoint dominating sets which are activated successively. The dominating sets do not guarantee the coverage of the whole region of interest. Abrams et al. (Abrams et al., 2004) design three approximation algorithms for a variation of the set k-cover problem, where the objective is to partition the sensors into covers such that the number of covers that include an area, summed over all areas, is maximized. Their work builds upon previous work in (Slijepcevic and Potkonjak, 2001) and the generated cover sets do not provide complete coverage of the monitoring zone.

In (Cardei and Du, 2005), the authors propose a heuristic to compute the disjoint set covers (DSC). In order to compute the maximum number of covers, they first transform DSC into a maximum-flow problem, which is then formulated as a mixed integer programming problem (MIP). Based on the solu-

tion of the MIP, they design a heuristic to compute the final number of covers. The results show a slight performance improvement in terms of the number of produced DSC in comparison to (Slijepcevic and Potkonjak, 2001) but it incurs higher execution time due to the complexity of the mixed integer programming resolution. Zorbas et al. (Zorbas et al., 2007) present B{GOP}, a centralized coverage algorithm introducing sensor candidate categorisation depending on their coverage status and the notion of critical target to call targets that are associated with a small number of sensors. The total running time of their heuristic is $O(mn^2)$ where n is the number of sensors, and m the number of targets. Compared to algorithm's results of Slijepcevic and Potkonjak (Slijepcevic and Potkonjak, 2001), their heuristic produces more cover sets with a slight growth rate in execution time.

In the case of non-disjoint algorithms (Chaudhary and Pujari, 2011), sensors may participate in more than one cover set. In some cases this may prolong the lifetime of the network in comparison to the disjoint cover set algorithms but designing algorithms for non-disjoint cover sets generally incurs a higher order of complexity. Moreover in case of a sensor's failure, non-disjoint scheduling policies are less resilient and less reliable because a sensor may be involved in more than one cover sets. For instance, Cardei et al. (Cardei et al., 2005) present a linear programming (LP) solution and a greedy approach to extend the sensor network lifetime by organizing the sensors into a maximal number of non-disjoint cover sets. Simulation results show that by allowing sensors to participate in multiple sets, the network lifetime increases compared with related work (Cardei and Du, 2005). In (Berman and Calinescu, 2004), the authors have formulated the lifetime problem and suggested another (LP) technique to solve this problem. A centralized provably near optimal solution based on the Garg-Könemann algorithm (Garg and Könemann, 1998) is also proposed.

3 ALGORITHMS DESCRIPTION

We try to produce an adaptive scheduling which allows sensors to operate alternatively so as to prolong the network lifetime. For convenience, the notations and assumptions are described first.

3.1 Notations and assumptions

- m : the number of targets
- n : the number of sensors

- K : maximal number of cover sets
- i : index of target ($i = 1..m$)
- j : index of sensor ($j = 1..n$)
- k : index of cover set ($k = 1..K$)
- T_0 : initial set of targets
- S_0 : initial set of sensors
- T : set of targets which are not covered by at least one cover set
- S : set of available sensors
- $S_0(i)$: set of sensors which cover the target i
- $T_0(j)$: set of targets covered by sensor j
- C_k : cover set of index k
- $T(C_k)$: set of targets covered by the cover set k
- $NS(i)$: set of available sensors which cover the target i
- $NC(i)$: set of cover sets which do not cover the target i
- $|\cdot|$: cardinality of the set

We assume that the lifetimes of sensors are identical. Lifetime of a sensor is time duration when the sensor is in the active state all the time. In order to achieve lifetime extension, sensors must be divided into a number of subsets, called cover sets, where each cover set is capable of monitoring all the targets. Sensors belonging to a scheduled cover set are in active mode, while the others are in sleep mode. If the cover sets are disjoint, then each sensor is allowed to participate only in one cover set. The maximal number of possible disjoint cover sets is given by :

$$K_{max} = \min_{i=1..m} |S_0(i)| \quad (1)$$

since each cover set must cover all targets and each sensor can only be part of one cover set.

3.2 Near optimal algorithm

The main idea of the algorithm is to build simultaneously the cover sets by adding gradually the sensors capable of monitoring the most critical target. At each iteration of the algorithm we compute the critical rate (let call it $R(i)$) of a target i as follows :

$$R(i) = \frac{|NS(i)|}{|NC(i)|} \quad (2)$$

Some targets may have the same critical rate. In this case, the choice of the most critical target is made randomly among these targets. When the most critical target has been identified, sensors monitoring this target have to be distributed in each cover set which does

Algorithm 1 Near optimal algorithm

Require: An initial set of targets T_0 and an initial set of sensors S_0

Ensure: A set of cover sets $C_1, \dots, C_{K_{max}}$

```

1: {INITIALIZATION}
2: for all cover sets  $k = 1..K_{max}$  do

5: end for
6:  $S \leftarrow S_0$ 
7:  $T \leftarrow T_0$ 
8: for all targets  $i = 1..m$  do
9:    $NC(i) \leftarrow \{C_1, \dots, C_{K_{max}}\}$ 
10:   $NS(i) \leftarrow S_0(i)$ 
11: end for
12: {While there exists a target which is not covered
    by a cover set and the set of available sensors is
    not empty}
13: while  $T \neq \emptyset$  and  $S \neq \emptyset$  do
14:   for all targets  $i \in T$  do
15:     Compute  $R(i) = \frac{|NS(i)|}{|NC(i)|}$ 
16:   end for
17:   {Choose the most critical target}
18:    $i^* = \min_{i \in T} R(i)$ 
19:   for all  $j \in NS(i^*)$  do
20:     Compute  $p_{jk} = |T_0(j) \cap \{T_0 \setminus T(C_k)\}|$  for
       each cover set  $C_k \in NC(i^*)$ 
21:   end for
22:   Solve the linear assignment problem to assign
       one sensor  $j \in NS(i^*)$  in each cover set  $k \in
       NC(i^*)$  with costs  $p_{jk}$ 
23:   Update  $C_k, T(C_k) \quad \forall k = 1..K_{max}$ 
24:   Update  $T, S$  and  $NS(i), NC(i) \quad \forall i \in T$ 
25: end while
26:  $K_1 \leftarrow K_{max}$ 
27: if  $T$  is not empty then
28:   for all  $i \in T$  do
29:     Delete the cover sets  $C_k \in NC(i)$ 
30:      $K_1 \leftarrow K_1 - 1$ 
31:   end for
32: end if

```

not already cover this target. This distribution can be made randomly or made soundly in order to cover a maximum number of targets in each cover set. That is why we give a cost p_{jk} for the possible assignment of the sensor j to a cover set C_k which represents the additional number of targets that the cover set C_k is able to monitor if the sensor j is added. We face a linear assignment problem where it is required to assign exactly one sensor to each cover set in such a way that the total cost of the assignment is maximized. In our case, the number of sensors to be assigned can be dif-

ferent to the number of cover sets. If the number of sensors is greater than the number of cover sets, we artificially add a new cover set and null costs between all sensors and this additional cover set to be reduced to a classical linear assignment problem. In contrast, if the number of sensors is less than the number of cover sets, we add a dummy sensor and null costs between this dummy sensor and the cover sets. During the process, if we face this second case, this means that some cover sets may not cover all the targets in the region of interest.

3.3 Example

To illustrate our algorithm we provide a simple example with only 20 sensors and 10 targets. Table 1 presents the sensors which are able to monitor each target.

Table 1: Collection of sensors to monitor a target

Target i	Sensors in $S_0(i)$
t_1	s_1, s_3, s_4, s_5
t_2	$s_6, s_8, s_{13}, s_{14}, s_{20}$
t_3	$s_2, s_5, s_9, s_{10}, s_{12}$
t_4	$s_1, s_6, s_7, s_8, s_{13}, s_{15}$
t_5	$s_4, s_{17}, s_{18}, s_{19}, s_{20}$
t_6	$s_2, s_5, s_{11}, s_{14}, s_{16}$
t_7	$s_8, s_9, s_{10}, s_{17}, s_{18}$
t_8	$s_6, s_7, s_{10}, s_{14}, s_{20}$
t_9	s_1, s_2, s_3, s_4, s_5
t_{10}	$s_2, s_4, s_8, s_{12}, s_{14}, s_{17}, s_{19}$

Here, the maximum number of possible generated cover sets is equal to $K = 4$. The most critical target is target 1. We assign randomly a sensor $j \in S_0(1)$ to each cover set ($k = 1..4$) as reported in table 2.

Table 2: Sensors and covered targets in each cover set

k	C_k	$T(C_k)$
1	s_1	$\{t_1, t_4, t_9\}$
2	s_3	$\{t_1, t_9\}$
3	s_4	$\{t_1, t_5, t_9, t_{10}\}$
4	s_5	$\{t_1, t_3, t_6, t_9\}$

We update $T \leftarrow T_0 \setminus \{t_1, t_9\}$, $S \leftarrow S_0 \setminus \{s_1, s_3, s_4, s_5\}$. Then we obtain new sets $NS(i)$ and $NC(i)$ for each target i (see table 3). We compute critical rates of targets which are reported in table 4.

The most critical targets are t_2, t_7 and t_8 as shown in table 4. We choose randomly target t_7 . We have to assign a sensor $j \in NS(7) = \{s_8, s_9, s_{10}, s_{17}, s_{18}\}$ to each cover set $k \in NC(7) = \{C_1, C_2, C_3, C_4\}$.

Table 3: Available sensors for the target and cover sets not monitoring the target

Target $i \in T$	$NS(i)$	$NC(i)$
t_2	$s_6, s_8, s_{13}, s_{14}, s_{20}$	$\{C_1, C_2, C_3, C_4\}$
t_3	s_2, s_9, s_{10}, s_{12}	$\{C_1, C_2, C_3\}$
t_4	$s_6, s_7, s_8, s_{13}, s_{15}$	$\{C_2, C_3, C_4\}$
t_5	$s_{17}, s_{18}, s_{19}, s_{20}$	$\{C_1, C_2, C_4\}$
t_6	$s_2, s_{11}, s_{14}, s_{16}$	$\{C_1, C_2, C_3\}$
t_7	$s_8, s_9, s_{10}, s_{17}, s_{18}$	$\{C_1, C_2, C_3, C_4\}$
t_8	$s_6, s_7, s_{10}, s_{14}, s_{20}$	$\{C_1, C_2, C_3, C_4\}$
t_{10}	$s_2, s_8, s_{12}, s_{14}, s_{17}, s_{19}$	$\{C_1, C_2, C_4\}$

Table 4: Critical rate of each non covered target

Target $i \in T$	$R(i)$
t_2	5/4
t_3	4/3
t_4	5/3
t_5	4/3
t_6	4/3
t_7	5/4
t_8	5/4
t_{10}	6/3

We compute $p_{jk} = |T_0(j) \cap \{T_0 \setminus T(C_k)\}|$ for each sensor $j \in NS(7)$ and for each $k \in NC(7)$. p_{jk} represents the additional number of targets that the cover set C_k is able to monitor if the sensor j is added to C_k . Linear assignment costs are given in table 5.

Table 5: Linear assignment costs

	C_1	C_2	C_3	C_4
s_8	3	4	3	4
s_9	2	2	2	1
s_{10}	3	3	3	2
s_{17}	3	3	1	3
s_{18}	1	1	1	1

An optimal solution for the linear assignment problem is to add the sensors s_{10}, s_8, s_9, s_{17} respectively to the cover sets C_1, C_2, C_3, C_4 . Note that there are multiple optimal solutions for this assignment problem. An other solution is s_{17} in C_1 , s_{10} in C_2 , s_9 in C_3 , and s_8 in C_4 . We update $T \leftarrow T \setminus \{t_7\}$, $S \leftarrow S \setminus \{s_{10}, s_8, s_9, s_{17}\}$ and we start the process again with new sets given in tables 6 and 7.

Table 6: Sensors and covered targets in each cover set

k	C_k	$T(C_k)$
1	$\{s_1, s_{10}\}$	$\{t_1, t_3, t_4, t_8, t_9\}$
2	$\{s_3, s_8\}$	$\{t_1, t_2, t_4, t_7, t_9, t_{10}\}$
3	$\{s_4, s_9\}$	$\{t_1, t_3, t_5, t_7, t_9, t_{10}\}$
4	$\{s_5, s_{17}\}$	$\{t_1, t_3, t_5, t_6, t_7, t_9, t_{10}\}$

Table 7: Available sensors for the target, cover sets not monitoring the target, and critical rates

Target $i \in T$	$NS(i)$	$NC(i)$	$R(i)$
t_2	$s_6, s_{13}, s_{14}, s_{20}$	$\{C_1, C_3, C_4\}$	4/3
t_3	s_2, s_{12}	$\{C_2\}$	2/1
t_4	s_6, s_7, s_{13}, s_{15}	$\{C_3, C_4\}$	4/2
t_5	s_{18}, s_{19}, s_{20}	$\{C_1, C_2\}$	3/2
t_6	$s_2, s_{11}, s_{14}, s_{16}$	$\{C_1, C_2, C_3\}$	4/3
t_8	s_6, s_7, s_{14}, s_{20}	$\{C_2, C_3, C_4\}$	4/3
t_{10}	$s_2, s_{12}, s_{14}, s_{19}$	$\{C_1\}$	4/1

The most critical targets are t_2 , t_6 and t_8 . We choose randomly target t_2 . We have to assign a sensor $j \in NS(2) = \{s_6, s_{13}, s_{14}, s_{20}\}$ to each cover set $k \in NC(2) = \{C_1, C_3, C_4\}$ with linear assignment costs given in table 8.

Table 8: Linear assignment costs

	C_1	C_3	C_4
s_6	1	3	3
s_{13}	1	2	2
s_{14}	3	3	2
s_{20}	2	2	2

An optimal solution for the linear assignment problem is to add the sensors s_{14}, s_{13}, s_6 respectively to the cover sets C_1, C_3, C_4 . We update $T \leftarrow T \setminus \{t_2, t_4, t_{10}\}$, $S \leftarrow S \setminus \{s_{14}, s_{13}, s_6\}$ and we start again with sets reported in tables 9 and 10.

Table 9: Sensors and covered targets in each cover set

k	C_k	$T(C_k)$
1	$\{s_1, s_{10}, s_{14}\}$	$\{t_1, t_2, t_3, t_4, t_6, t_8, t_9, t_{10}\}$
2	$\{s_3, s_8\}$	$\{t_1, t_2, t_4, t_7, t_9, t_{10}\}$
3	$\{s_4, s_9, s_{13}\}$	$\{t_1, t_2, t_3, t_4, t_5, t_7, t_9, t_{10}\}$
4	$\{s_5, s_{17}, s_6\}$	$\{t_1, t_2, t_3, t_4, t_5, t_6, t_7, t_8, t_9, t_{10}\}$

The most critical target is t_8 . We have to assign a sensor $j \in NS(8) = \{s_7, s_{20}\}$ to each cover set $k \in NC(2) = \{C_2, C_3\}$. Costs are given in table 11.

Table 10: Available sensors for the target, cover sets not monitoring the target, and critical rates

Target $i \in T$	$NS(i)$	$NC(i)$	$R(i)$
t_3	s_2, s_{12}	$\{C_2\}$	2/1
t_5	s_{18}, s_{19}, s_{20}	$\{C_1, C_2\}$	3/2
t_6	s_2, s_{11}, s_{16}	$\{C_2, C_3\}$	3/2
t_8	s_7, s_{20}	$\{C_2, C_3\}$	2/2

Table 11: Linear assignment costs

	C_2	C_3
s_7	1	1
s_{20}	2	1

We assign sensor s_7 to the cover set C_3 and the sensor s_{20} to the cover set C_2 . Statements (line 23 and 24 of the algorithm 1) allow us to obtain new sets given in tables 12 and 13. This leads to a new invocation of the loop.

Table 12: Available sensors for the target and cover sets not monitoring the target

k	C_k	$T(C_k)$
1	$\{s_1, s_{10}, s_{14}\}$	$\{t_1, t_2, t_3, t_4, t_6, t_8, t_9, t_{10}\}$
2	$\{s_3, s_8, s_{20}\}$	$\{t_1, t_2, t_4, t_5, t_7, t_8, t_9, t_{10}\}$
3	$\{s_4, s_9, s_{13}, s_7\}$	$\{t_1, t_2, t_3, t_4, t_5, t_7, t_8, t_9, t_{10}\}$
4	$\{s_5, s_{17}, s_6\}$	$\{t_1, t_2, t_3, t_4, t_5, t_6, t_7, t_8, t_9, t_{10}\}$

Table 13: Available sensors for the target, cover sets not monitoring the target, and critical rates

Target $i \in T$	$NS(i)$	$NC(i)$	$R(i)$
t_3	s_2, s_{12}	$\{C_2\}$	2/1
t_5	s_{18}, s_{19}	$\{C_1\}$	2/1
t_6	s_2, s_{11}, s_{16}	$\{C_2, C_3\}$	3/2

The most critical target is t_6 (see column 3 of table 13). We have to assign a sensor $j \in NS(6) = \{s_2, s_{11}, s_{16}\}$ to each cover set $k \in NC(6) = \{C_2, C_3\}$. The assignment costs p_{jk} are given in table 14.

We assign sensor s_2 to the cover set C_2 and the sensor s_{11} to the cover set C_3 and we obtain the cover sets $C_k, (k = 1..K_{max})$ given in table 15.

Now only target t_5 is not covered in the cover set C_1 . We have the choice between s_{18} or s_{19} to complete the cover set C_1 .

Table 14: Linear assignment costs

	C_2	C_3
s_2	2	1
s_{11}	1	1
s_{16}	1	1

Table 15: Sensors and covered targets in each cover set

k	C_k	$T(C_k)$
1	$\{s_1, s_{10}, s_{14}\}$	$\{t_1, t_2, t_3, t_4, t_6, t_8, t_9, t_{10}\}$

3.4 Algorithm's analysis

We express the time complexity of our algorithm 1 by using the following notations :

$$v = \max(|S|, |T|) = \max(n, m) \quad (3)$$

and :

$$S_{max} = \max_{i=1..m} |S_0(i)| \quad (4)$$

The time complexity of our algorithm is at most

$$O\left(v(|T| + K_{max}S_{max} + S_{max}^3 + K_{max} + |T|)\right) \quad (5)$$

Proof. The main computational cost of the algorithm is spent in the while loop (lines 13 to 25). This loop is executed $v = \max(|S|, |T|)$ times. The inner loop (lines 14 to 16) cost at most $O(|T|)$ since the criticalness of all the targets in T need to be computed at each iteration. Line 18 takes $O(|T|)$ for finding the most critical target. The inner loop (lines 19 to 21) costs $|NS(i^*)| \times |NC(i^*)|, i^* \in T$, since the cost p_{jk} of each target $j \in NS(i^*)$ needs to be computed on each cover set $k \in NC(i^*)$. However, we can bound both $|NS(i^*)|$ and $|NC(i^*)|$ by S_{max} and K_{max} respectively. Thus, the cost of this loop is at most $O(S_{max}K_{max})$. Finally, the line statement 22 is equivalent to a linear assignment problem, which can be found in polynomial time, for instance using the Hungarian method (Harold W. Kuhn, 1955). Thereby, the linear assignment problem of line 22 takes at most $O(S_{max}^3)$, since we can bound both $|NS(i^*)|$ and $|NC(i^*)|$ by S_{max} . Updating steps (lines 23 and 24) require $O(K_{max} + |T|)$ iterations. Thus, summing up for the whole v loops/iterations, the algorithm's cost is at most

$$O\left(v(|T| + K_{max}S_{max} + S_{max}^3 + K_{max} + |T|)\right)$$

Since $K_{max} \leq S_{max} \leq |S| \leq v$, and $|T| \leq v$, we can derive the upper bound $O(v^4)$. \square

3.5 Randomized algorithm

Here, we give only a simple proposal of the algorithm which constructs in parallel the elementary cover sets as sketched in algorithm 2. Our goal is not to give the best implementation, but only a possible implementation in order to compare the lower bounds to the ones obtained by algorithm 1.

Unlike algorithm 1, the randomized algorithm chooses randomly a non covered target and tries to assign a sensor covering this target to each cover set if necessary. We use the same structure of algorithm 1. This choice is made to demonstrate the relevance of the selection/assignment policy of algorithm 1.

Algorithm 2 Randomized algorithm

Require: An initial set of targets T_0 and an initial set of sensors S_0

Ensure: A set of cover sets C_1, \dots, C_{K_2}

```

1: {INITIALIZATION}
2: for all cover sets  $k = 1..K_{max}$  do
3:    $C_k \leftarrow \emptyset$ 
4:    $T(C_k) \leftarrow \emptyset$ 
5: end for
6:  $S \leftarrow S_0$ 
7:  $T \leftarrow T_0$ 
8: for all targets  $i = 1..m$  do
9:    $NC(i) \leftarrow \{C_1, \dots, C_{K_{max}}\}$ 
10:   $NS(i) \leftarrow S_0(i)$ 
11: end for
12: {While there exists a target which is not covered
    by a cover set and the set of available sensors is
    not empty}
13: while  $T \neq \emptyset$  and  $S \neq \emptyset$  do
14:   Choose randomly a target  $i^*$  in  $T$ 
15:   Assign randomly one sensor  $j \in NS(i^*)$  in each
       cover set  $k \in NC(i^*)$ 
16:   Update  $C_k, T(C_k) \quad \forall k = 1..K_{max}$ 
17:   Update  $T, S$  and  $NS(i), NC(i), \quad \forall i \in T$ 
18: end while
19:  $K_2 \leftarrow K_{max}$ 
20: if  $T$  is not empty then
21:   for all  $i \in T$  do
22:     Delete the cover sets  $C_k \in NC(i)$ 
23:      $K_2 \leftarrow K_2 - 1$ 
24:   end for
25: end if
```

3.6 Exact Method

In this section, we present how to deduce the optimal number of disjoint cover sets once we applied each of the previous algorithms. We obtain an approximated

solution with algorithm 1 or with the randomized algorithm and we denote by $K_{min} = \max\{K_1, K_2\}$ the achieved number of disjoint cover sets, where K_1 corresponds to the number of disjoint cover sets obtained with algorithm 1 and K_2 to the number of disjoint cover sets obtained with the randomized algorithm. As the optimal number of disjoint cover sets K_{opt} is bounded by $K_{max} = \min_{1..m} |S_0(i)|$, we deduce that $K_{min} \leq K_{opt} \leq K_{max}$. The intuitive idea is to deduce K_{opt} by performing a binary search between K_{min} and K_{max} . At each step of the search process, we check if there exists a partition of the sensors in K cover sets. Once the number of disjoint cover sets is fixed to K , the distribution of sensors among the K cover sets is given by the resolution of the following integer programming (IP) problem:

$$\begin{cases} \min 1 \\ \text{subject to :} \\ \sum_{j \in S_0(i)} y_{jk} \geq 1, \quad \forall i \in T_0, \forall k \in K \\ \sum_{k=1..K} y_{jk} \leq 1, \quad \forall j \in S_0 \\ y_{jk} \in \{0, 1\} \end{cases} \quad (6)$$

The decision variables y_{jk} are binary variables which are equal to 1 if the sensor j belongs to the cover set k and 0 otherwise. Note that there is no real objective function. We only try to find a distribution of the sensors over K cover sets which satisfies some constraints. The first constraint ensures that all targets are covered in each cover set $k = 1..K$. The second constraint forces each sensor to be in only one cover set. For a given number K of cover sets, it may happen that the problem has no solution. In this case, we decrement K and we solve again the problem (6). To compute K_{opt} , we perform a binary search as presented in algorithm 3.

Note that the integer programming problem (6) which is solved at each iteration of the binary search process, to reach the optimal solution, is known to be NP-hard (Garey and Johnson, 1990). We use a Branch-and-Bound method to solve it, and we have interest that algorithm 1 provides the best lower bound to avoid additional iterations for the resolution of the integer programming problem.

4 RESULTS

In this section we evaluate the performance of our algorithms by way of simulations. We simulate a network with sensor nodes and target points randomly located in a $500m \times 500m$ area. We assume the sensing range is equal for all the sensors in the network and is set to $150m$. In the different scenarios we vary the number of randomly deployed sensor nodes n be-

Algorithm 3 Exact Method - binary search

Require: A set of targets T_0 , a set of sensors S_0

Ensure: A set of cover sets $C_1, C_2, \dots, C_{K_{opt}}$

```
 $K_{opt} \leftarrow K_{min}$ 
while  $K_{min} \neq K_{max}$  do
   $K \leftarrow \lceil \frac{K_{min} + K_{max}}{2} \rceil + 1$ 
  Solve (6)
  if (6) has no solution then
     $K_{max} \leftarrow K$ 
  else
     $K_{min} \leftarrow K$ 
     $K_{opt} \leftarrow K$ 
    Optimal solution  $y_{jk}^*$  of (6) are saved
  end if
end while
for all  $k = 1..K_{opt}$  do
   $C_k \leftarrow \cup_{(s_j/y_{jk}^*=1)} \{s_j\}$ 
end for
```

tween 50 and 200 with an increment of 50. The number m of targets to be covered varies between 30 and 120 with an increment of 30. The following requirements are satisfied: each sensor covers at least one target and each target is covered by at least one deployed sensor, the connectivity of the network is ensured and all sensors are capable of communicating with the base station. For a given number of sensors and targets, we generate 100 random topologies of network. Our experiments have been conducted on a regular Linux workstation with a AMD Athlon(tm) 64 X2 Dual Core Processor 4000+ of 2,1 GHz. The resolution of the integer programming problem is carried out by the Branch-and-Bound method implemented in GLPK (GNU linear Programming Kit) (Mahkorin, 2010) available in the public domain.

Note that for convenience and sake of simplicity, there is no need to conduct comparison with previous works in the literature since the obtained results are compared to the optimal ones achieved by the exact method.

4.1 Number of disjoint cover sets

We measure the average number of disjoint cover sets $\bar{K}_1, \bar{K}_2, \bar{K}_{opt}$ over the 100 instances for the algorithm 1, the randomized algorithm and the exact method. As algorithm 1 and the randomized algorithm integrate a random part, they are executed 50 times for each network topology of each scenario. Table 16 summarizes the obtained results. Results of table 16 are consistent with those obtained in the literature (Cardei and Du, 2005). The number of disjoint cover sets increases with sensor density, and decreases as the num-

ber of targets goes up for a fixed number of sensors. This is explained by the fact that sensors are more requested. The obtained results show that our algorithm 1 has a very good behavior because it is able to achieve near optimal solution compared to the optimal one obtained by the exact method in almost all simulated cases. On the other side a simple randomized algorithm provides solutions which are far more than 15% of the optimum and this gap, computed as $\frac{\bar{K}_{opt} - \bar{K}_2}{\bar{K}_{opt}}$, grows when the number of sensors and targets increases to reach 38% with 200 sensors and 120 targets.

Table 16: Number of disjoint cover sets

N	M	\bar{K}_2	\bar{K}_1	\bar{K}_{opt}
50	30	2.97	3.46	3.46
	60	2.44	2.96	2.96
	90	2.19	2.60	2.60
	120	2.06	2.49	2.49
100	30	7.16	8.84	8.84
	60	5.54	7.54	7.54

150	30	10.75	13.50	13.50
	60	8.80	12.03	12.03
	90	7.89	11.34	11.34
	120	7.42	10.91	10.91
200	30	14.53	19.03	19.03
	60	11.65	16.94	16.98
	90	10.44	16.11	16.11
	120	9.67	15.53	15.59

4.2 Comparison of the execution times

In this section, we compare and comment the CPU execution times of the different resolution methods. Table 17 gives the distribution of the execution times (in seconds) for the three methods over the 16 scenarios. Note that the method called "exact method" consists in performing a binary search between K_{min} and K_{max} and in solving an integer programming problem at each iteration. To assess the efficiency of our algorithm 1, we distinguish two cases for the reporting execution times of the exact method. In the first case, K_{min} is given by the number of disjoint cover sets (K_2) obtained by the randomized algorithm, and in the second case, the binary search begins with $K_{min} = K_1$.

From table 17, we can see that the running times increase with both sensor and target density as expected (see the time complexity value in section 3.4). If the optimal value of the number of disjoint cover

Table 17: Execution times (in seconds) for the 3 methods

N	M	Randomized algorithm 2	Heuristic algorithm 1	Exact method ($K_{min} = K_1$)	Exact method ($K_{min} = K_2$)
50	30	0.010	0.023	0.000	0.026
	60	0.019	0.031	0.000	0.053
	90	0.026	0.037	0.000	0.058
	120	0.036	0.046	0.000	0.030

	90	0.086	0.205	0.000	3.540
	120	0.118	0.227	0.000	4.070
150	30	0.041	0.503	0.000	17.478
	60	0.100	0.653	0.000	25.733
	90	0.160	0.698	0.000	42.646
	120	0.222	0.768	0.000	58.182
200	30	0.063	1.270	0.000	123.600
	60	0.150	1.660	16.190	251.467
	90	0.250	1.730	0.000	345.877
	120	0.352	1.936	83.26	543.568

sets is reached with our algorithm 1, then no resolution of the integer programming is involved again. This leads to the execution times which are equal to zero (column 5 of table 17). Moreover, the resolution of integer programming is time consuming and the involved binary search task to compute the optimal value by starting with random solution may require more than 9 minutes as the number of sensors/targets goes up.

5 CONCLUSIONS

In this paper, we have addressed the problem of lifetime optimization in wireless sensor networks. This is a very natural and important problem, as sensor nodes have limited resources in terms of memory, energy and computational power. To cope with this problem, an efficient centralized energy-aware algorithm is presented and analyzed. Our algorithm seeks to prolong the network lifetime by organizing sensors into disjoint cover sets which operate successively in order to monitor all targets. Our algorithm involves a linear assignment problem to generate mutually disjoint cover sets containing a minimal number of sensors and covering a maximal number of targets at each iteration. Simulation results highlight the good behaviour of our algorithm, which provides near optimal solutions (equal to the optimal ones achieved by the exact method for almost all scenarios) with minimum time complexity. The quality of the obtained lower bound reduces significantly the search for the optimal

number of cover sets, because this search process requires the resolution of an integer programming problem which is time-consuming.

Our future work will explore other possible strategies to guide our algorithm and to test it on larger instances. Another open area of further study is to adapt our algorithm so that the partition of the sensors into disjoint cover sets meet different objectives.
